# BOUNDEDNESS AND MODULI OF TRADITIONAL STABLE MINIMAL MODELS

#### XIAOWEI JIANG

ABSTRACT. Recently, for good minimal models with semi-log canonical (slc) singularities, polarized by effective divisors that are relatively ample over the bases of Iitaka fibration, Birkar proves that they belong to a bounded family after fixing appropriate numerical invariants, and then he constructs their projective coarse moduli spaces. In this paper, we consider good minimal models with only Kawamata log terminal (klt) singularities but polarized by possibly non-effective divisors. We prove that they still belong to a bounded family after fixing the same invariants. As an application, we construct separated coarse moduli spaces for klt good minimal models polarized by line bundles.

## 1. Introduction

Throughout this paper, we work over an algebraically closed field k of characteristic zero unless otherwise stated.

The central problem in birational geometry is the classification of algebraic varieties. According to the standard Minimal Model Conjecture and Abundance Conjecture, any variety is birational to either a Mori fiber space or a good minimal model. Therefore, the next main goal of birational geometry is to construct moduli spaces for these objects. For this purpose, one big problem is whether or not there are only finitely many families for these objects after fixing certain numerical invariants, i.e., they belong to a bounded family. In this paper, we will focus on good minimal models, that is, varieties with semi-ample canonical divisors.

For canonical polarized varieties, i.e., ample models of good minimal models with maximal Kodaira dimension, the projective coarse moduli spaces of these varieties have been established in any dimension by the contributions of many people over the past three decades [KSB88, Kol90, Ale94, KM97, Fuj18, KP17, Kol23]. Notably, advancements in the higher-dimensional minimal model program [BCHM10, Bir12, HX13, HMX13, HMX14, HMX18] have played a crucial role in these developments, particularly in the boundedness and properness of the relevant moduli functors.

For Calabi-Yau varieties, i.e., good minimal models with Kodaira dimension zero, there is no natural choice of polarization. In general, they are not bounded in the category of algebraic varieties. For example, projective K3 surfaces and abelian varieties of any fixed dimension are not bounded. Nevertheless, there have been some recent progresses toward (birational) boundedness of elliptic Calabi-Yau varieties and rationally connected Calabi-Yau varieties, see [BDCS20, FHS21, Bir23c].

When studying moduli of Calabi-Yau varieties, a polarization is typically fixed despite the non-uniqueness of the choice. Various techniques, such as GIT, Hodge theory, minimal model program and mirror symmetry, have been applied to study the moduli of polarized Calabi-Yau varieties and have been successful in specific examples; refer to [Ale02, Laz16, HKY20, Oda22, ADL23, AE23, ABB+23] for a partial list. Recently, Birkar establishes a boundedness result for slc (resp. klt) Calabi-Yau varieties polarized by effective (resp. possibly non-effective) ample Weil divisors with fixed volume in any dimension, and it is crucial for constructing their projective (resp. separated) coarse moduli spaces [Bir23b].

For good minimal models with arbitrary non-negative Kodaira dimension, Birkar has recently proven a boundedness result for slc good minimal models polarized by effective Weil divisors that are relatively ample over the bases of Iitaka fibration, and he has constructed their projective coarse moduli spaces [Bir22]. This achievement is based on a series of recent works [BZ16, Bir19, Bir21c, Bir23b, Bir21a, BH22]. When restricted to good minimal models with maximal Kodaira dimension, he also obtains a new moduli

functor for varieties whose canonical divisors are nef and big but not ample, a similar construction in this case has appeared in the work of Filipazzi-Inchiostro [FI21].

The reason for taking effective divisors as polarization in [Bir22] is that one can obtain proper or even projective moduli spaces. However, this often leads to larger moduli spaces than desired, as it also parametrizes all the additional effective divisors. Traditionally, people use line bundles as polarization, although it is difficult to meaningfully compactify these moduli spaces. For example, Viehweg considers ample line bundles as polarization for treating the moduli of smooth good minimal models [Vie95]. Then Taji constructs moduli of good minimal models with canonical singularities [Taj20]. More recently, Hashizume-Hattori consider klt good minimal models of Kodaira dimension one, polarized by line bundles that are relatively ample over the bases of Iitaka fibration [HH23].

One naturally wonders if there exists a boundedness result for klt good minimal models of arbitrary Kodaira dimension, polarized by line bundles that are relatively ample over the bases of the Iitaka fibration. This paper addresses this question in a more general context and proceeds to construct their coarse moduli spaces.

1.1. **Traditional stable minimal models.** We define the main object studied in this paper, as introduced in Birkar's survey note [Bir23a].

**Definition 1.1.** A traditional stable minimal model (X, B), A over k consists of a projective connected pair (X, B) and  $\mathbb{Q}$ -Cartier Weil divisor A (not necessarily effective) such that

- $\bullet$  (X,B) is klt,
- $K_X + B$  is semi-ample defining a contraction  $f: X \to Z$ , and
- $K_X + B + tA$  is ample for some t > 0.

We usually denote the model by (X, B), A or more precisely (X, B),  $A \to Z$ . We say (X, B), A is strongly traditional stable if in addition  $K_X + B + A$  is ample.

Note that we do not assume that A is ample globally. Indeed, if  $X \to Z$  is the contraction defined by  $K_X + B$ , then  $K_X + B + tA$  being ample for some t > 0 is equivalent to the fact that A is ample over Z. Moreover, t is not fixed in our setting.

The terminology "traditional" originates from our adoption of the traditional approach, wherein we consider using a line bundle or, more generally, a possibly non-effective  $\mathbb{Q}$ -Cartier Weil divisor as the polarization. When (X,B) is slc, and we choose an effective divisor A as the polarization such that (X,B+tA) is slc for some t>0, then (X,B), A is referred to as a *stable minimal model* in [Bir22].

**Definition 1.2.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{>0}$  be a finite set,  $u, v, \lambda \in \mathbb{Q}^{>0}$ , and  $\sigma \in \mathbb{Q}[t]$  be a polynomial. We will define various classes of traditional stable minimal models.

- (1) A  $(d, \Phi)$ -traditional stable minimal model is a traditional stable minimal model (X, B), A such that
  - $\dim X = d$ , and

• the coefficients of B are in  $\Phi$ .

The set of all the  $(d, \Phi)$ -traditional stable minimal models is denoted by  $\mathcal{TS}_{klt}(d, \Phi)$ .

- (2) A  $(d, \Phi, u, v)$ -traditional stable minimal model is a  $(d, \Phi)$ -traditional stable minimal model (X, B), A such that
  - $\operatorname{vol}(A|_F) = u$ , where F is any general fiber of  $f: X \to Z$ , and
  - $Ivol(K_X + B) = v$  (see Definition 2.2).

Let  $\mathcal{TS}_{klt}(d, \Phi, u, v)$  denote the set of all  $(d, \Phi, u, v)$ -traditional stable minimal models.

- (3) A  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model is a  $(d, \Phi)$ -traditional stable minimal model (X, B), A such that
  - $\operatorname{vol}(A|_F) \in \Gamma$ , where F is any general fiber of  $f: X \to Z$ , and
  - we have

$$vol(K_X + B + tA) = \sigma(t)$$
, for all  $0 \le t \ll 1$ .

Let  $\mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  denote the set of all  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal models.

(4) A  $(d, \Phi, \Gamma, \sigma, \lambda)$ -traditional stable minimal model is a  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model (X, B), A such that  $K_X + B + \lambda A$  is big (and hence  $K_X + B + tA$  is big for any  $0 < t \le \lambda$ ).

Let  $\mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma, \lambda)$  denote the set of all  $(d, \Phi, \Gamma, \sigma, \lambda)$ -traditional stable minimal models.

**Example 1.3.** Given a  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model (X, B), A, if A is a pseudo-effective  $\mathbb{Q}$ -Cartier Weil divisor, then (X, B), A is a  $(d, \Phi, \Gamma, \sigma, 1)$ -traditional stable minimal model. Indeed,

$$K_X + B + A = K_X + B + \epsilon A + (1 - \epsilon)A$$

for some  $0 < \epsilon \ll 1$ , then  $K_X + B + \epsilon A$  is ample and  $(1 - \epsilon)A$  is pseudo-effective, thus  $K_X + B + A$  is big. In particular, a klt stable minimal model (X, B), A as defined in [Bir22] is a  $(d, \Phi, \Gamma, \sigma, 1)$ -traditional stable minimal model.

1.2. Boundedness of traditional stable minimal models. We define the notion of boundedness of traditional stable minimal models and then state one of the main results of this paper.

**Definition 1.4** (Boundedness of traditional stable minimal models). A subset  $\mathcal{E} \subset \mathcal{TS}_{klt}(d,\Phi)$  is said to be a bounded family if there is a fixed  $r \in \mathbb{N}$  such that for any (X,B), A in  $\mathcal{E}$  we can find a very ample divisor H on X satisfying

$$H^d \leq r, (K_X + B) \cdot H^{d-1} \leq r$$
 and  $H - A$  is pseudo-effective.

This in particular bounds  $(X, \operatorname{Supp} B)$ . If in addition A is effective, then  $(X, \operatorname{Supp} (B+A))$  belongs to a bounded family.

Our definition of boundedness slightly differs from the original definition in [Bir22, Section 2.9]. In [Bir22], Birkar assumes A to be an effective divisor, then the notion of boundedness is defined as follows: a subset  $\mathcal{E} \subset \mathcal{TS}_{klt}(d, \Phi)$  is said to be a bounded family if there is a fixed  $r \in \mathbb{N}$  such that for any (X, B), A in  $\mathcal{E}$  we can find a very ample divisor H on X satisfying

$$H^d \le r$$
 and  $(K_X + B + A) \cdot H^{d-1} \le r$ .

The requirements of our definition imply that of his, and by [Bir22, Lemma 4.6], they are equivalent when A is an effective divisor with coefficients belonging to a DCC set.

**Theorem 1.5.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{> 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Then  $\mathcal{TS}_{klt}(d,\Phi,\Gamma,\sigma)$  is a bounded family.

Birkar has proved this theorem when dim Z=0 (see Theorem 3.3), and it plays a crucial role in the partial compactification of moduli spaces of Calabi-Yau varieties [Oda22, Oda21]. When dim Z=1, Hashizume-Hattori show that the set of (X,B) appearing in  $\mathcal{TS}_{klt}(d,\Phi,u,v)$  belongs to a log bounded family [HH23, Theorem 1.4] without using the polynomial  $\sigma$ , and then they construct their coarse moduli spaces. Recently, there have been some other related results on the (birational) boundedness of klt good minimal models, see [FS20, Fil20, FHS21, Jia22, Zhu23].

Conjecturally, we can remove the condition on  $vol(A|_F)$ , which is related to the effective b-semiampleness conjecture [PS09, Conjecture 7.13]. For related discussions, refer to [Bir21a, Bir22].

1.3. Moduli of traditional stable minimal models. We will use the boundedness result from the previous subsection to construct moduli spaces for traditional stable minimal models. We firstly define families of traditional minimal models and the corresponding moduli functors. See Section 2.3 for the relevant definitions of families of pairs over reduced bases.

### **Definition 1.6.** Let S be a reduced Noetherian scheme over k.

- (1) When  $S = \operatorname{Spec} K$  for a field K, we define a traditional stable minimal model over K as in Definition 1.1 by replacing k with K and replacing connected with geometrically connected. Similarly we can define  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal models over K.
- (2) A family of traditional stable minimal models over S consists of a projective morphism  $X \to S$  of schemes, a  $\mathbb{Q}$ -divisor B and a line bundle A on X such that
  - $(X, B) \to S$  is a locally stable family,
  - $(X_s, B_s), A_s$  is a traditional stable minimal model over k(s) for every  $s \in S$ . Here  $X_s$  is the fiber of  $X \to S$  over s and  $B_s$  is the divisorial pullback of B to  $X_s$ .  $K_{X_s} + B_s$  is semi-ample defining a contration  $X_s \to Z_s$ ,  $A_s$  is a line bundle on  $X_s$  which is relatively ample over  $Z_s$ . We will denote the family by  $(X, B), A \to S$ .

- (3) Let  $d \in \mathbb{N}$ ,  $\Phi = \{a_1, a_2, \dots, a_m\}$ , where  $a_i \in \mathbb{Q}^{\geq 0}$ ,  $\Gamma \subset \mathbb{Q}^{\geq 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. A family of  $(d, \Phi, \Gamma, \sigma)$ -marked traditional stable minimal models over S is a family of traditional stable minimal models  $(X, B), A \to S$  such that
  - $B = \sum_{i=1}^{m} a_i D_i$ , where  $D_i \ge 0$  are relative Mumford divisors, and
  - $(X_s, B_s), A_s$  is a  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model over k(s) for every  $s \in S$ , where  $B_s = \sum_{i=1}^m a_i D_{i,s}$ .
- (4) We define the moduli functor  $\mathfrak{TS}_{klt}(d,\Phi,\Gamma,\sigma)$  of  $(d,\Phi,\Gamma,\sigma)$ -traditional stable minimal models from the category of reduced Noetherian schemes to the category of groupoids by choosing
  - On objects: for a reduced Noetherian scheme S, one take  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(S)$
  - ={family of  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal models over S}.

We define an isomorphism  $(f': (X', B'), A' \to S) \to (f: (X, B), A \to S)$  of any two objects in  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(S)$  to be an S-isomorphism  $\alpha_X: (X', B') \to (X, B)$  such that  $A' \sim_S \alpha_X^* A$ .

• On morphisms:  $(f_T: (X_T, B_T), A_T \to T) \to (f: (X, B), A \to S)$  consists of morphisms of schemes  $\alpha: T \to S$  such that the natural map  $g: X_T \to X \times_S T$  is an isomorphism,  $B_T$  is the divisorial pullback of B and  $A_T \sim_T g^*\alpha_X^*A$ . Here  $\alpha_X: X \times_S T \to X$  is the base change of  $\alpha$ .

Now we can state our main result on moduli.

**Theorem 1.7.**  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is a separated Deligne-Mumford stack of finite type, which admits a coarse moduli space  $TS_{klt}(d, \Phi, \Gamma, \sigma)$  as a separated algebraic space.

Acknowledgement. The author expresses gratitude to his advisor Professor Caucher Birkar for generously sharing his survey note [Bir23a], which formulate the question addressed in this work. He also appreciates Professor Caucher Birkar for constant support and helpful discussions. He thanks Professor Junchao Shentu for inspiring discussions on [She23], motivating the author to consider the problem in this paper. He thanks Junpeng Jiao, Santai Qu, Minzhe Zhu and Yu Zou for reading a draft of this paper and providing valuable comments. He also thanks Bingyi Chen and Jia Jia for useful comments on the first version of this paper.

## 2. Preliminaries

- 2.1. **Notations and conventions.** We collect some notations and conventions used in this paper.
  - (1) A projective morphism  $f: X \to Y$  of schemes is called a *contraction* if  $f_*\mathcal{O}_X = \mathcal{O}_Y$  (f is not necessarily birational). In particular, f is surjective with connected fibers.
  - (2) For any scheme S and positive integer n, l, we denote  $\mathbb{P}_k^n \times_{\operatorname{Spec} k} S$  and  $\mathbb{P}_k^l \times_{\operatorname{Spec} k} S$  by  $\mathbb{P}_S^n$  and  $\mathbb{P}_S^l$ , respectively. When  $S = \operatorname{Spec} k$ , we simply write  $\mathbb{P}^n$  and  $\mathbb{P}^l$  if there

is no risk of confusion. Let  $\mathbb{P}^n_S \times_S \mathbb{P}^l_S \cong \mathbb{P}^n \times \mathbb{P}^l \times S$  be the natural isomorphism, and

$$\mathbb{P}^n \stackrel{p_1}{\leftarrow} \mathbb{P}^n \times \mathbb{P}^l \times S \stackrel{p_2}{\rightarrow} \mathbb{P}^l$$

be the projections. Then for any  $a, b \in \mathbb{Z}$ , we denote  $p_1^* \mathcal{O}_{\mathbb{P}^n}(a) \otimes p_2^* \mathcal{O}_{\mathbb{P}^l}(b)$  by  $\mathcal{O}_{\mathbb{P}^n \times \mathbb{P}^l \times S}(a, b)$ .

- (3) We say that a surjective morphism  $f: S' \to S$  between schemes is an étale covering if  $S' := \bigsqcup_{i \in I} S_i$ , and  $f|_{S_i}: S_i \to S$  is étale for any  $i \in I$ . Given a covering  $S' \to S$ , we will use the convention that  $S_{ij}$  denotes  $S_i \times_S S_j$  and  $S_{ijk}$  denotes  $S_i \times_S S_j \times_S S_k$ .
- (4) Let  $f: X \to S$  be a morphism of schemes. Let  $L_1$  and  $L_2$  be line bundles on X. We say that  $L_1$  and  $L_2$  are linearly equivalent over S, denoted by  $L_1 \sim_S L_2$ , if there is a line bundle M on S such that  $L_1 \cong L_2 \otimes f^*M$ .
- (5) Suppose that X is a normal variety. Let  $D_1$  and  $D_2$  be  $\mathbb{Q}$ -Cartier  $\mathbb{Q}$ -divisors on X. We say that  $D_1$  and  $D_2$  are  $\mathbb{Q}$ -linear equivalent, denoted by  $D_1 \sim_{\mathbb{Q}} D_2$ , if there exists  $m \in \mathbb{Z}_{>0}$  such that  $mD_1$  and  $mD_2$  are Cartier and  $mD_1 \sim mD_2$ . Moreover, fixed  $l \in \mathbb{Z}_{>0}$ , the notation  $D_1 \sim_l D_2$  means that  $lD_1 \sim_l D_2$ .
- (6) We say that a line bundle L on a variety X is strongly ample if L is very ample and  $H^q(X, kL) = 0$  for any k, q > 0.
- (7) We say that a set  $\Phi \subset \mathbb{Q}$  satisfies the descending chain condition (DCC, for short) if  $\Phi$  does not contain any strictly decreasing infinite sequence. Similarly, we say that a set  $\Phi \subset \mathbb{Q}$  satisfies the ascending chain condition (ACC, for short) if  $\Phi$  does not contain any strictly increasing infinite sequence.
- (8) A pair (X, B) consists of a normal variety X and a boundary divisor B with rational coefficients in [0, 1] such that  $K_X + B$  is  $\mathbb{Q}$ -Cartier. Fixed  $\epsilon \in \mathbb{Q}^{>0}$ , singularities of (X, B) are defined by taking a log resolution  $\phi : W \to X$  and writing

$$K_W + B_W = \phi^*(K_X + B).$$

We say (X, B) is lc (resp.  $\epsilon$ -lc) (resp. klt) if every coefficient of  $B_W$  is  $\leq 1$  (resp.  $\leq 1 - \epsilon$ ) (resp. < 1).

2.2. **Volume of divisors.** We define various kinds of volumes for divisors. In this paper, we mainly consider  $\mathbb{Q}$ -divisors. However, for the proof of Proposition 3.9, we need to deal with  $\mathbb{R}$ -divisors.

**Definition 2.1** (Volumes). Let X be a normal irreducible projective variety of dimension d, and let D be an  $\mathbb{R}$ -divisor on X. The *volume* of D is

$$vol(X, D) = \limsup_{m \to \infty} \frac{d!h^0(X, \mathcal{O}_X(\lfloor mD \rfloor))}{m^d}.$$

**Definition 2.2** (Iitaka volumes). Let X be a normal irreducible projective variety of dimension d, and let D be an  $\mathbb{R}$ -divisor on X such that Iitaka dimension  $\kappa(D)$  is nonnegative. Then the *Iitaka volume* of D, denoted by Ivol(D), is

$$Ivol(D) = \limsup_{m \to \infty} \frac{\kappa(D)! h^0(X, \mathcal{O}_X(\lfloor mD \rfloor))}{m^{\kappa(D)}}.$$

**Definition 2.3** (Restricted volumes). Let X be a normal irreducible projective variety of dimension d, and let D be an  $\mathbb{R}$ -divisor on X. Let  $S \subset X$  be a normal irreducible subvariety of dimension n. Suppose that S is not contained in the augmented base locus  $\mathbf{B}_{+}(D)$ . Then the restricted volume of D along S is

$$\operatorname{vol}_{X|S}(D) = \limsup_{m \to \infty} \frac{n! (\dim \operatorname{Im}(H^0(X, \mathcal{O}_X(\lfloor mD \rfloor)) \to H^0(S, \mathcal{O}_S(\lfloor mD \rvert_S \rfloor))))}{m^n}.$$

For the precise definition of the augmented base locus  $\mathbf{B}_{+}(D)$ , see [ELM<sup>+</sup>06]. In this paper, we only use the fact that  $\mathbf{B}_{+}(D)$  is a Zariski-closed proper subset of X if and only if D is big. The restricted volume  $\operatorname{vol}_{X|S}(D)$  measures asymptotically the number of sections of the restriction  $\mathcal{O}_{S}(\lfloor mD \vert_{S} \rfloor)$  that can be lifted to X. If D is ample, then the restriction maps are eventually surjective, and hence

$$\operatorname{vol}_{X|S}(D) = \operatorname{vol}(D|_S).$$

In general, it can happen that  $\operatorname{vol}_{X|S}(D) < \operatorname{vol}(D|_S)$ .

**Theorem 2.4** ([LM09, Corollary 4.27]). Let X be an irreducible projective variety of dimension d, and let  $S \subset X$  be an irreducible (and reduced) Cartier divisor on X. Suppose that D is a big  $\mathbb{R}$ -divisor such that  $S \nsubseteq \mathbf{B}_+(D)$ . Then the function  $t \mapsto \operatorname{vol}(D+tS)$  is differentiable at t=0, and

$$\frac{\mathrm{d}}{\mathrm{d}t}(\mathrm{vol}(D+tS))\Big|_{t=0} = d\,\mathrm{vol}_{X|S}(D).$$

By [LM09, Remark 4.29], volume function has continuous partials in all directions at any point  $D \in \text{Big}(X)$ , i.e., the function vol :  $\text{Big}(X) \to \mathbb{R}$  is  $\mathcal{C}^1$ .

2.3. **Family of pairs.** In this subsection, we define a family of pairs over reduced base scheme. We firstly recall the notion of relative Mumford divisor from [Kol23, Definition 4.68].

**Definition 2.5** (Relative Mumford divisor). Let  $f: X \to S$  be a flat finite type morphism with  $S_2$  fibers of pure dimension d. A subscheme  $D \subset X$  is a relative Mumford divisor if there is an open set  $U \subset X$  such that

- $\operatorname{codim}_{X_s}(X_s \setminus U_s) \ge 2$  for each  $s \in S$ ,
- $D|_U$  is a relative Cartier divisor,
- D is the closure of  $D|_U$ , and
- $X_s$  is smooth at the generic points of  $D_s$  for every  $s \in S$ .

By  $D|_U$  being relative Cartier we mean that  $D|_U$  is a Cartier divisor on U and that its support does not contain any irreducible component of any fiber  $U_s$ .

If  $D \subset X$  is a relative Mumford divisor for  $f: X \to S$  and  $T \to S$  is a morphism, then the divisorial pullback  $D_T$  on  $X_T := X \times_S T$  is the relative Mumford divisor defined to be the closure of the pullback of  $D|_U$  to  $U_T$ . In particular, for each  $s \in S$ , we define  $D_s = D|_{X_s}$  to be the closure of  $D|_{U_s}$  which is the divisorial pullback of D to  $X_s$ .

**Definition 2.6** (Locally stable family). A locally stable family of projective klt pairs  $(X, B) \to S$  over a reduced Noetherian scheme S is a flat finite type morphism  $X \to S$  with  $S_2$  fibers and a  $\mathbb{Q}$ -divisor B on X satisfying

- each prime component of B is a relative Mumford divisor,
- $K_{X/S} + B$  is Q-Cartier, and
- $(X_s, B_s)$  is a klt pair for any point  $s \in S$ .

# 3. Boundedness

In this section, we will prove boundedness of traditional stable minimal models with fixed data.

3.1. Boundedness of generalised klt pairs. The bases of traditional stable minimal models are generalised klt pairs, we refer readers to [BZ16, Bir21b] for the background of the theory of generalised pairs and their singularities. We recall notions and boundedness results about generalised pairs.

**Definition 3.1.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set, and  $v \in \mathbb{Q}^{>0}$ . Let  $\mathcal{F}_{gklt}(d, \Phi, v)$  be the set of projective generalised pairs (X, B + M) with nef part M' such that

- (X, B + M) is generalised klt of dimension d,
- the coefficients of B are in  $\Phi$ ,
- $M' = \sum \mu_i M'_i$  where  $\mu_i \in \Phi$  and  $M'_i$  are nef Cartier, and
- $K_X + B + M$  is ample with volume  $vol(K_X + B + M) = v$ .

The following theorem, although not explicitly stated in this form, is due to [Bir21a].

**Theorem 3.2.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set, and  $u, v \in \mathbb{Q}^{>0}$ . Then there exists  $l \in \mathbb{N}$  depending only on  $d, \Phi, u, v$  such that for any traditional stable minimal model

$$(X,B), A \to Z \in \mathcal{TS}_{klt}(d,\Phi,u,v),$$

we can write an adjunction formula

$$K_X + B \sim_l f^*(K_Z + B_Z + M_Z)$$

such that the corresponding set of generalized pairs  $(Z, B_Z + M_Z)$  forms a bounded family. Moreover,  $l(K_Z + B_Z + M_Z)$  is very ample.

Proof. By applying [Bir23b, Corollary 1.4] to  $(F, B|_F)$ ,  $A|_F$ , we can find  $m \in \mathbb{Z}_{>0}$ , depending only on d,  $\Phi$  such that  $H^0(F, \mathcal{O}_X(mA|_F)) \neq 0$ . Thus we have  $G \sim mA$  for some Weil divisor G whose horizontal part, which we denote by E, is an effective Weil divisor. By applying [Bir21a, Lemma 7.4] to  $f: (X, B), E \to Z$ , there exist  $p, q \in \mathbb{N}$  depending only on d,  $\Phi$ , u such that we can write an adjunction formula

$$K_X + B \sim_q f^*(K_Z + B_Z + M_Z),$$

where  $B_Z$  (resp.  $M_Z$ ) is the discriminant part (resp. moduli part) of the canonical bundle formula such that  $pM_{Z'}$  is Cartier on some higher resolution  $Z' \to Z$ .

By definition of the discriminant part of the canonical bundle formula and the ACC for lc thresholds [HMX14, Theorem 1.1], we see that the coefficients of  $B_Z$  belong to a DCC subset of  $\mathbb{Q}^{>0}$  depending only on d and  $\Phi$ , which we denote by  $\Psi$ . Moreover,  $(Z, B_Z + M_Z)$  is generalised klt pair and

$$Ivol(K_X + B) = vol(K_Z + B_Z + M_Z) = v.$$

Adding  $\frac{1}{p}$ , we can assume  $\frac{1}{p} \in \Psi$ , we see that

$$(Z, B_Z + M_Z) \in \mathcal{F}_{qklt}(\dim Z, \Psi, v).$$

By [Bir21a, Theorem 1.4], the set of generalized pairs  $(Z, B_Z + M_Z)$  forms a bounded family. By the argument after [Bir22, Theorem 4.3], there exists  $l \in \mathbb{N}$  depending only on dim  $Z, \Psi, v$ , hence depending only on  $d, \Phi, u, v$  such that  $l(K_Z + B_Z + M_Z)$  is very ample. Replacing q, l with ql, we conclude the proof.

3.2. Boundedness of traditional stable Calabi-Yau pairs. The fibers of traditional stable minimal models are so-called *traditional stable Calabi-Yau pairs*, i.e., klt Calabi-Yau pairs polarized by possibly non-effective ample Weil divisors.

**Theorem 3.3** ([Bir23b, Corollary 1.6]). Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{>0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Consider those

$$(X,B), A \to Z \in \mathcal{TS}_{klt}(d,\Phi,\Gamma,\sigma)$$

with dim Z = 0. Then such (X, B), A form a bounded family.

*Proof.* This is a special case of Theorem 3.7.

3.3. Boundedness of traditional stable minimal models. In this subsection, we prove Theorem 1.5.

The following crucial result is a key ingredient in the proof of Theorem 1.5. It indicates that the singularities of the pairs (X, B) can be controlled uniformly. Moreover, the coefficients of B belong to a fixed finite set.

**Lemma 3.4.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set, and  $u, v \in \mathbb{Q}^{>0}$ . Then the set

$$\{a(D, X, B) \le 1 | (X, B), A \in \mathcal{TS}_{klt}(d, \Phi, u, v), D \text{ prime divisor over } X\}$$

is finite.

Proof. By applying [Bir23b, Corollary 1.4] to  $(F, B|_F)$ ,  $A|_F$ , we can find  $m \in \mathbb{Z}_{>0}$ , depending only on d,  $\Phi$  such that  $H^0(F, \mathcal{O}_X(mA|_F)) \neq 0$ . Thus we have  $G \sim mA$  for some Weil divisor G whose horizontal part, which we denote by E, is an effective Weil divisor. By applying [Bir21a, Lemma 8.2] to  $f: (X, B), E \to Z$  (the proof uses E only in the relative sense over E, the condition of E0, E1 belong to a fixed finite set depending only on E1, E2 only in the interval E3, E4 belong to a fixed finite set depending only on E4, E5.

We can recover some invariants of a  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model from the given data  $(d, \Phi, \Gamma, \sigma)$  by the following lemma.

**Lemma 3.5.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{> 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Then for any

$$(X, B), A \to Z \in \mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma),$$

• we have

$$\sigma(t) = \sum_{i=0}^{d} {d \choose i} (K_X + B)^{d-i} \cdot A^i t^i,$$

hence for  $0 \le i \le d$ , the intersection numbers  $(K_X + B)^{d-i} \cdot A^i$  are uniquely determined by d and  $\sigma$ .

- $d \dim Z$  is the smallest degree of t that appears in  $\sigma$ .
- For a general fiber F of  $X \to Z$ , we have

$$(K_X + B)^{\dim Z} \cdot A^{d - \dim Z} = \text{Ivol}(K_X + B) \text{vol}(A|_F).$$

*Proof.* This is [Bir22, Lemma 4.12], the condition that A is effective is not used in his proof.

First, we consider a special case of Theorem 1.5, where we add the condition that  $K_X + B + A$  is ample. We recall the notation of a set of strongly traditional stable minimal models with fixed data, and then we prove that it belongs to a bounded family.

**Definition 3.6.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $u, v \in \mathbb{Q}^{>0}$ , and  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Recall that a strongly traditional stable minimal model is a traditional stable minimal model (X, B), A such that  $K_X + B + A$  is ample. A  $(d, \Phi, u, v, \sigma)$ - strongly traditional stable minimal model is a strongly traditional stable minimal model (X, B), A such that

- $\bullet$  dim X = d,
- the coefficients of B are in  $\Phi$ ,
- $\operatorname{vol}(A|_F) = u$ , where F is any general fiber of  $f: X \to Z$ ,
- $\text{Ivol}(K_X + B) = v$ , and
- $vol(K_X + B + tA) = \sigma(t)$ , for all  $t \in [0, 1]$ .

Let  $\mathcal{STS}_{klt}(d, \Phi, u, v, \sigma)$  denote the set of all  $(d, \Phi, u, v, \sigma)$ -strongly traditional stable minimal models.

**Theorem 3.7.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $u, v \in \mathbb{Q}^{>0}$ , and  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Then  $\mathcal{STS}_{klt}(d, \Phi, u, v, \sigma)$  is a bounded family.

Proof. Pick  $(X, B), A \in \mathcal{STS}_{klt}(d, \Phi, u, v, \sigma)$ , let  $f: X \to Z$  be the contraction defined by the semi-ample divisor  $K_X + B$ . By Lemma 3.4, the log discrepancies of (X, B) in the interval [0, 1] belong to a fixed finite set depending only on  $d, \Phi, u, v$ . Therefore, (X, B)is  $\epsilon$ -lc and  $l(K_X + B)$  is integral for some  $\epsilon > 0$  and  $l \in \mathbb{N}$  depending only on  $d, \Phi, u, v$ . Let  $N := l(K_X + B + A)$  be an ample Q-Cartier Weil divisor, then

$$vol(K_X + B + N) = (l+1)^d vol(K_X + B + \frac{l}{l+1}A) = (l+1)^d \sigma(\frac{l}{l+1})$$

is fixed. Thus by [Bir23b, Theorem 1.5], the set of (X, B) forms a log bounded family.

Since  $\mathcal{P} = \{(X, B)\}$  is a set of  $\epsilon$ -lc pairs that belongs to a log bounded family, by [HLQ23, Theorem 1.10], for any  $\mathbb{Q}$ -Cartier Weil divisor D on X,  $I_0D$  is Cartier for some  $I_0 \in \mathbb{N}$  depending only on  $\epsilon$  and  $\mathcal{P}$  and hence depending only on d,  $\Phi$ , u, v,  $\sigma$ . Let

$$L := 2l(K_X + B) + lA$$

be an ample Q-Cartier Weil divisor, then  $I_0L$  is an ample Cartier divisor. We see that

$$I_0L - (K_X + B) = (I_0l - 1)(K_X + B) + I_0l(K_X + B + A)$$

is nef and big, then by effective base point freeness theorem [Kol93, Theorem 1.1], there exists a positive integer  $I_1$  depending only on d,  $I_0$  such that  $I_1L$  is base point free. Since  $I_1L - (K_X + B)$  is nef and big, by very ampleness lemma [Fuj17, Lemma 7.1], there exists a positive integer I depending only on d,  $I_1$  and hence depending only on  $I_2$ 0,  $I_3$ 1 and hence depending only on  $I_3$ 2 such that  $I_3$ 3 is very ample. Note that

$$vol(IL) = (2Il)^d vol(K_X + B + \frac{1}{2}A) = (2Il)^d \sigma(\frac{1}{2})$$

is fixed, and  $(K_X + B) \cdot (IL)^{d-1}$  is determined by  $\sigma(t)$  by Lemma 3.5. Also we see that

$$IL - A = (Il + 1)(K_X + B) + (Il - 1)(K_X + B + A)$$

is pseudo-effective. Let H be a general element of |IL|, then (X, B), A belongs to a bounded family in the sense of Definition 1.4.

Under the condition that  $K_X + B + \lambda A$  is big for some positive rational number  $\lambda$  (and hence  $K_X + B + tA$  is big for any  $0 < t \le \lambda$ ), we can reduce Theorem 1.5 to Theorem 3.7 by the following theorem. We follow the argument of [Bir22, Proof of Theorem 4.1] with some modifications. In Step 6 of the proof of the following theorem, since we are dealing with a possibly non-effective big Weil divisor, after replacing it with an effective  $\mathbb{Q}$ -divisor in the  $\mathbb{Q}$ -linear system, we may lose control of its coefficients. Therefore, we require a stronger boundedness result on singularities, as discussed in [Bir21c, Theorem 1.8], compared to the one presented in [Bir22, Lemma 4.7]. This motivates the modification of the definition of boundedness for traditional stable minimal models in our context (Definition 1.4) from the original definition in [Bir22, Section 2.9].

**Theorem 3.8.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{> 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial,  $\lambda \in \mathbb{Q}^{> 0}$ . Then there is a positive rational number  $\tau \in (0,1]$  depending only on  $d, \Phi, \Gamma, \sigma, \lambda$  such that  $K_X + B + \tau A$  is ample for all

$$(X, B), A \in \mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma, \lambda).$$

Moreover,  $\mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma, \lambda)$  is a bounded family.

*Proof.* We prove theorem by induction on dimension of X.

Step 1. Choose

$$(X, B), A \to Z \in \mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma, \lambda).$$

By Lemma 3.5, for a general fiber F of  $X \to Z$ ,  $Ivol(K_X + B) vol(A|_F)$  is a fixed number depending only on d and  $\sigma$ . Since  $vol(A|_F)$  belongs to a finite set  $\Gamma$ , there are finitely many possibilities for  $Ivol(K_X + B)$ . Therefore, we may fix both  $u = vol(A|_F)$  and  $v = Ivol(K_X + B)$ .

Again by Lemma 3.5,

$$\sigma(t) = \sum_{i=0}^{d} {d \choose i} (K_X + B)^{d-i} \cdot A^i t^i,$$

and the intersection numbers  $(K_X+B)^{d-i}\cdot A^i$  are determined by d and  $\sigma$  for any  $0\leq i\leq d$ . Step 2. By Lemma 3.4, we may choose an  $\alpha\in\mathbb{N}$  depending only on  $d,\Phi,u,v,\lambda$  such that  $\alpha(K_X+B+\lambda A)$  is a big Weil divisor. Moreover, for  $0\leq t\ll 1,\,K_X+B+t\alpha(K_X+B+\lambda A)$  is ample and

$$\operatorname{vol}(K_X + B + t\alpha(K_X + B + \lambda A))$$

$$= \operatorname{vol}((1 + t\alpha)(K_X + B) + t\alpha\lambda A)$$

$$= ((1 + t\alpha)(K_X + B) + t\alpha\lambda A)^d$$

is a polynomial  $\gamma$  in t whose coefficients are uniquely determined by the intersection numbers  $(K_X + B)^{d-i} \cdot A^i$ ,  $\alpha$  and  $\lambda$ . Therefore,  $\gamma$  is determined by  $d, \Phi, \Gamma, \sigma, \lambda$ .

Replacing  $A, u, \sigma$  with  $\alpha(K_X + B + \lambda A), (\alpha \lambda)^{\dim F} u, \gamma$ , we may assume that A is a big Weil divisor, and

$$(X,B), A \in \mathcal{TS}_{klt}(d,\Phi,\Gamma,\sigma,1).$$

Step 3. If  $K_X + B + A$  is ample, i.e., (X, B), A is a strongly traditional stable minimal model, then for any  $t \in [0, 1]$ ,

$$vol(K_X + B + tA) = (K_X + B + tA)^d$$

is a polynomial in t in the interval [0,1]. Thus for every  $t \in [0,1]$ ,

$$\operatorname{vol}(K_X + B + tA) = \sigma(t)$$

since both sides of the equality are polynomials which agree for t sufficiently small. Thus by Theorem 3.7, (X, B), A is bounded in the sense of Definition 1.4. In particular, when  $\dim X = 1$ ,  $K_X + B + A$  is ample, the theorem holds.

Step 4. From now on we assume that dim  $X \geq 2$ . Our goal is to find a positive rational number  $\tau \in (0,1]$  depending only on  $d, \Phi, \Gamma, \sigma$  such that  $K_X + B + \tau A$  is ample. Once this condition is guaranteed, then by Lemma 3.4, we may choose  $\beta \in \mathbb{N}$  depending only on  $d, \Phi, u, v, \tau$  such that  $\beta(K_X + B + \tau A)$  is an ample Weil Divisor. By the same argument as Step 2, after replacing  $A, u, \sigma$  with  $\beta(K_X + B + \tau A), (\beta \tau)^{\dim F} u, \zeta$ , where  $\zeta$  is a polynomial in t determined by  $d, \sigma, \tau$ , and  $\beta$ , we may assume that A is an ample Weil divisor, and

(X,B), A is strongly traditional stable belonging to

$$\mathcal{STS}_{klt}(d, \Phi, u, v, \sigma).$$

Hence by Step 3, (X, B), A belongs to a bounded family in the sense Definition 1.4.

We claim that it is enough to find  $\tau \in (0,1]$  depending only on  $d, \Phi, \Gamma, \sigma$  such that  $K_X + B + \tau A$  is nef. Indeed, we can show that  $K_X + B + tA$  is ample for any  $t \in (0,\tau)$ : we may pick  $0 < t' \ll t$  such that  $K_X + B + t'A$  is ample by Definition 1.1, then  $K_X + B + tA$  is a positive linear combination of  $K_X + B + t'A$  and  $K_X + B + \tau A$ , hence it is ample. So replacing  $\tau$  with  $\frac{\tau}{2}$  we can assume that  $K_X + B + \tau A$  is ample. We aim to find such  $\tau$  in the subsequent steps.

Step 5. By Definition 1.1,  $K_X + B$  is semi-ample defining the contraction  $f: X \to Z$ . If  $\dim Z = 0$ , then (X, B), A is a traditional stable Calabi-Yau pair belonging to a bounded family by Theorem 3.3. We can assume that  $\dim Z > 0$ . By Theorem 3.2, there exists  $l \in \mathbb{N}$  depending only on  $d, \Phi, u, v$  such that we can write an adjunction formula

$$K_X + B \sim_l f^*(K_Z + B_Z + M_Z)$$

and the generalised klt pair  $(Z, B_Z + M_Z)$  belongs to a bounded family. Moreover,

$$L := l(K_Z + B_Z + M_Z)$$

is very ample.

Let T be a general member of |L| and let S be its pullback to X. Define

$$K_S + B_S = (K_X + B + S)|_S$$

and  $A_S = A|_S$ . Then  $(S, B_S), A_S \to T$  is a traditional stable minimal model: indeed, we may choose a general  $T \in |L|$  such that (X, B + S) is plt, hence  $(S, B_S)$  is a projective klt pair. Moreover,  $K_S + B_S$  is semi-ample defining the contraction  $g: S \to T$ , and  $K_S + B_S + tA_S$  is ample for every small t > 0 since  $K_X + B + S + tA$  is ample for every small t > 0.

If G is a general fiber of  $S \to T$ , then

$$\operatorname{vol}(A_S|_G) = \operatorname{vol}(A|_G) = u,$$

since G is among the general fibers of  $X \to Z$ . Moreover, for  $0 \le t \ll 1$ , we have

$$\psi(t) = \text{vol}(K_S + B_S + tA_S)$$

$$= \text{vol}((K_X + B + S + tA)|_S)$$

$$= (K_X + B + S + tA)^{d-1} \cdot S$$

$$= ((l+1)(K_X + B) + tA)^{d-1} \cdot S$$

$$= ((l+1)(K_X + B) + tA)^{d-1} \cdot l(K_X + B),$$

where  $\psi(t)$  is a polynomial in t whose coefficients are uniquely determined by the intersection numbers  $(K_X + B)^{d-i} \cdot A^i$  and by l, and hence by  $d, \sigma, l$ . Furthermore, since S is the pullback of a general element of a very ample linear system,  $A_S = A|_S$  is still a

big Weil divisor. Thus  $(S, B_S)$ ,  $A_S$  is a traditional stable minimal model belonging to

$$\mathcal{TS}_{klt}(d-1,\Phi,\Gamma,\psi,1).$$

Therefore,  $(S, B_S)$ ,  $A_S$  belongs to a bounded family in the sense of Definition 1.4 by induction.

Step 6. By Lemma 3.5,  $(S, B_S)$ ,  $A_S$  is a traditional stable minimal model belonging to

$$\mathcal{TS}_{klt}(d-1,\Phi,u,v')$$

for some fixed  $v' = \text{Ivol}(K_S + B_S)$  that depends on  $d, \sigma, u$ . Then  $(S, B_S)$  is  $\epsilon$ -lc for some  $\epsilon \in \mathbb{Q}^{>0}$  depending only on  $d-1, \Phi, u, v'$  by Lemma 3.4. By Step 5,  $(S, B_S), A_S$  belongs to a bounded family in the sense of Definition 1.4, hence there is a fixed  $r \in \mathbb{N}$  such that for any  $(S, B_S), A_S$ , we can find a very ample divisor  $H_S$  on S satisfying

$$H_S^{d-1} \leq r, (K_S + B_S) \cdot H_S^{d-2} \leq r, \text{ and } H_S - A_S \text{ is pseudo-effective.}$$

By [Bir22, Lemma 4.6], we may assume that  $H_S - B_S$  is pseudo-effective. Since A is big, there is an effective  $\mathbb{Q}$ -divisor E such that  $A \sim_{\mathbb{Q}} E$ . Since S is a pullback of a general element of a very ample linear system,  $E_S := E|_S$  is an effective  $\mathbb{Q}$ -divisor and  $A_S \sim_{\mathbb{Q}} E_S$ . Moreover,  $H_S - E_S \sim_{\mathbb{Q}} H_S - A_S$  is also pseudo-effective.

Thus by [Bir21c, Theorem 1.8], there is a fixed  $\tau \in \mathbb{Q}^{>0}$  depending only on  $d-1, \epsilon, r$  such that

$$lct(S, B_S, |E_S|_{\mathbb{Q}}) > \tau,$$

hence  $(S, B_S + \tau E_S)$  is klt. Then by inversion of adjunction [KM98, Theorem 5.50],  $(X, B + S + \tau E)$  is plt near S. Therefore,  $(X, B + \tau E)$  is lc over the complement of a finite set of closed points of Z: otherwise, the non-lc locus of  $(X, B + \tau E)$  maps onto a closed subset of Z positive dimension which intersects T, hence S intersects the non-lc locus of  $(X, B + \tau E)$ , a contradiction.

Step 7. In this step, we assume that  $K_X + B + \tau E$  is not nef. Otherwise,  $K_X + B + \tau A \sim_{\mathbb{Q}} K_X + B + \tau E$  is nef, and we are done by Step 4.

Let R be a  $(K_X + B + \tau E)$ -negative extremal ray, since  $K_X + B + \tau E$  is ample over Z, R is not contained in fibers of  $X \to Z$ . Since  $K_X + B$  is the pullback of ample divisor on Z,  $(K_X + B) \cdot R > 0$ . By Step 6, the non-lc locus of  $(X, B + \tau E)$  maps to finitely many points of Z, so R is not contained in the image

$$\operatorname{Im}(\overline{\operatorname{NE}}(\Pi) \to \overline{\operatorname{NE}}(X)),$$

where  $\Pi$  is the non-lc locus of  $(X, B + \tau E)$ .

Then by the the length of extremal ray [Fuj11, Theorem 1.1], R is generated by a curve C with

$$(K_X + B + \tau E) \cdot C \ge -2d.$$

Since L is very ample,  $f^*L \cdot C = L \cdot f_*C \ge 1$ , we see that

$$(K_X + B + 2df^*L + \tau E) \cdot C \ge 0.$$

It follows that

$$K_X + B + 2df^*L + \tau E$$

is nef. Since  $f^*L \sim l(K_X + B)$ , we see that

$$K_X + B + \frac{\tau}{1 + 2dl} E \sim_{\mathbb{Q}} \frac{1}{1 + 2dl} (K_X + B + 2df^*L + \tau E)$$

is nef. Hence after replacing  $\tau$  with  $\frac{\tau}{1+2dl}$ , we can assume that  $K_X + B + \tau E$  is nef.  $\square$ 

To find a positive rational number  $\lambda$  such that  $K_X + B + \lambda A$  is big for any  $(X, B), A \to Z \in \mathcal{S}_{klt}(d, \Phi, \Gamma, \sigma)$ , one way is to focus on the volume function  $\theta(t) = \operatorname{vol}(K_X + B + tA)$ , as its graph provide information about the big thresholds of  $K_X + B$  with respect to A. However, in our setting, we only fix the top self-intersection number function  $\sigma(t) = (K_X + B + tA)^d$ . The idea is to compare  $\sigma(t)$  with  $\theta(t)$ . Since  $\sigma(t) = \theta(t)$  for  $0 < t \ll 1$ , we can compare them by investigating their derivatives. For the purpose of simplifying the computation, we will consider the variations of the volume function  $\vartheta(t)$  and the top self-intersection function  $\varsigma(t)$  instead.

**Proposition 3.9.** Let  $d \in \mathbb{N}$ ,  $\Phi \subset \mathbb{Q}^{\geq 0}$  be a DCC set,  $\Gamma \subset \mathbb{Q}^{>0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Then for any

$$(X, B), A \to Z \in \mathcal{TS}_{klt}(d, \Phi, \Gamma, \sigma),$$

there is a positive rational number  $\lambda$  depending only on  $d, \Phi, \Gamma, \sigma$  such that  $K_X + B + tA$  is big for all  $0 < t < \lambda$ .

*Proof. Step 1.* Let  $\varsigma \in \mathbb{Q}[t]$  be a polynomial function such that  $\varsigma(t) = \operatorname{vol}(A + t(K_X + B))$  for  $t \gg 1$ . We have

$$\varsigma(t) = (A + t(K_X + B))^d = \sum_{i=0}^d {d \choose i} A^{d-i} \cdot (K_X + B)^i t^i$$

for all t, since both left hand and right hand side of the equality are polynomials in t that agree for all large values of t. By Lemma 3.5,  $\varsigma$  is determined by  $\sigma$ . Again by Lemma 3.5, we may fix both  $u = \operatorname{vol}(A|_F)$  and  $v = \operatorname{Ivol}(K_X + B)$ . It is enough to show that there exists a positive rational number  $\tau$  depending only on d,  $\Phi$ ,  $\Gamma$ ,  $\sigma$  such that  $A + t(K_X + B)$  is big for all  $t > \tau$ . Let  $\vartheta(t) = \operatorname{vol}(A + t(K_X + B))$  be a function on t, then  $\vartheta(t)$  is a non-negative non-decreasing real function on t, which agrees with  $\varsigma(t)$  for  $t \gg 0$ . It suffices to show that  $\vartheta(t) > 0$  for all  $t > \tau$ .

Step 2. We prove this proposition by induction on the dimension of Z. By Lemma 3.5, dim Z is determined by  $\sigma$ , we may assume that dim Z = m is fixed. If dim Z = 0, then (X, B), A is a stable Calabi-Yau pair, proposition holds trivially. We may assume that dim Z > 0.

If  $\dim Z = 1$ , then

$$\varsigma(t) = (A + t(K_X + B))^d = A^d + dA^{d-1} \cdot (K_X + B)t = A^d + duvt.$$

Let  $\varsigma'(t)$  be the derivative of  $\varsigma(t)$  with respect to t, then  $\varsigma'(t) = duv$ . Let F be a general fiber of  $X \to Z$ , then we see that

$$K_X + B \sim_{\mathbb{Q}} f^*(K_Z + B_Z + M_Z) \sim_{\mathbb{Q}} vF$$

and we have

$$\vartheta(t) = \operatorname{vol}(A + t(K_X + B)) = v^d \operatorname{vol}(\frac{1}{v}A + tF).$$

For each t such that  $A + t(K_X + B)$  is big, i.e.,  $\vartheta(t) > 0$ , we may choose a sufficiently general fiber  $F_t$  of  $X \to Z$  such that  $F_t \nsubseteq \mathbf{B}_+(\frac{1}{v}A + tF_t)$ . Then by Theorem 2.4, the function  $s \mapsto \operatorname{vol}(\frac{1}{v}A + tF_t + sF_t)$  is differentiable at s = 0.

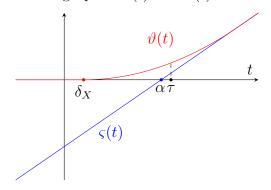

Let  $\vartheta'(t)$  be the derivative of  $\vartheta(t)$  with respect to t, we have

$$\left. \frac{1}{v^d} \vartheta'(t) = \frac{1}{v^d} \frac{\mathrm{d}}{\mathrm{d}s} \vartheta(t+s) \right|_{s=0} = \left. \frac{\mathrm{d}}{\mathrm{d}s} (\operatorname{vol}(\frac{1}{v}A + tF_t + sF_t)) \right|_{s=0} = d \operatorname{vol}_{X|F_t}(\frac{1}{v}A + tF_t),$$

hence

$$\vartheta'(t) = dv^d \operatorname{vol}_{X|F_t}(\frac{1}{v}A + tF_t) \le dv^d \operatorname{vol}((\frac{1}{v}A + tF_t)|_{F_t}) = dv^d \frac{1}{v^{d-1}}u = duv = \varsigma'(t).$$

FIGURE 1. The graph of  $\varsigma(t)$  and  $\vartheta(t)$  when dim Z=1

Let  $\alpha$  be the root of  $\varsigma(t)$  and  $\tau = \max\{\lceil \alpha \rceil + 1, 1\}$ , then  $\tau$  is a positive rational number. Let  $\delta_X$  be the real number such that  $\vartheta(t) = 0$  for all  $t \leq \delta_X$  and  $\vartheta(t) > 0$  for all  $t > \delta_X$ , where  $\delta_X$  may depend on X. We claim that  $\vartheta(\tau) > 0$ . Otherwise,  $\vartheta(\tau) = 0$ , and so  $\tau \leq \delta_X$ . Since  $\vartheta(t)$  agrees with  $\varsigma(t)$  for all  $t \gg 0$ , there exists a real number  $\delta_X' \gg 0$  ( $\delta_X'$  may depend on X a priori) such that  $\vartheta(\delta_X') = \varsigma(\delta_X')$ . By [Laz04, Corollary 2.2.45],  $\vartheta(t)$  is a continuous function. Since both  $\varsigma(t)$  and  $\vartheta(t)$  are differentiable in  $(\delta_X, \delta_X')$ , by [Rud76, Theorem 5.9], there is a point  $\gamma_X \in (\delta_X, \delta_X')$  at which

$$[\vartheta(\delta_X') - \vartheta(\delta_X)]\varsigma'(\gamma_X) = [\varsigma(\delta_X') - \varsigma(\delta_X)]\vartheta'(\gamma_X).$$

Since  $\vartheta(\delta_X') = \varsigma(\delta_X')$ ,  $\vartheta(\delta_X) = 0$  and  $\varsigma(\delta_X) \ge \varsigma(\tau) > 0$ , it follows that  $\vartheta'(\gamma_X) > \varsigma'(\gamma_X)$ , but by the previous paragraph,  $\vartheta'(t) \le \varsigma'(t)$  on  $(\delta_X, +\infty)$ , which is a contradiction. Therefore,  $\vartheta(\tau) > 0$ , and we can conclude that  $\vartheta(t) \ge \vartheta(\tau) > 0$  for all  $t > \tau$ .

Step 3. From now on we assume that  $\dim Z = m > 1$ . Recall that in the Step 5 of the proof of Theorem 3.8, we pick a general element T in the very ample linear system

 $|l(K_Z + B_Z + M_Z)|$  and let S be its pullback to X, then

$$S \sim_{\mathbb{Q}} l(K_X + B).$$

Define

$$K_S + B_S = (K_X + B + S)|_S$$

and  $A_S = A|_S$ , then

$$K_S + B_S \sim_{\mathbb{Q}} (\frac{1}{l} + 1)S|_S.$$

Moreover,  $(S, B_S), A_S \to T$  is a traditional stable minimal model belonging to

$$\mathcal{TS}_{klt}(d-1,\Phi,\Gamma,\psi)$$

for some fixed polynomial  $\psi(t) \in \mathbb{Q}[t]$  that depends on  $d, \Phi, \Gamma, \sigma$ , and dim T = m - 1. By induction, there is a positive rational number  $\lambda'$  depending only on  $d, \Phi, \Gamma, \sigma$  such that  $K_S + B_S + tA_S$  is big for all  $0 < t < \lambda'$ . Hence by Theorem 3.8, there is a positive rational number  $\beta$  depending only on  $d, \Phi, \Gamma, \sigma$  such that  $A_S + t(K_S + B_S)$  is ample for all  $t > \beta$ . Step 4. We have

$$\varsigma(t) = (A + t(K_X + B))^d 
= A^d + {d \choose 1} A^{d-1} \cdot (K_X + B)t + \dots + {d \choose m} A^{d-m} \cdot (K_X + B)^m t^m.$$

Let  $\varsigma'(t)$  be the derivative of  $\varsigma(t)$  with respect to t, if  $t > \beta(l+1)$ , then  $A_S + \frac{t}{l+1}(K_S + B_S)$  is ample by Step 3, we have

$$\varsigma'(t) = \binom{d}{1} A^{d-1} \cdot (K_X + B) + \dots + m \binom{d}{m} A^{d-m} \cdot (K_X + B)^m t^{m-1} 
= dA^{d-1} \cdot (K_X + B) + \dots + d \binom{d-1}{m-1} A^{d-m} \cdot (K_X + B)^{m-1} \cdot (K_X + B) t^{m-1} 
= d(A + t(K_X + B))^{d-1} \cdot (K_X + B) 
= \frac{d}{l} (A + t(K_X + B))^{d-1} \cdot S 
= \frac{d}{l} (A_S + \frac{t}{l+1} (K_S + B_S))^{d-1} 
> 0.$$

Hence  $\varsigma(t)$  is an increasing function on  $(\beta(l+1), +\infty)$ .

If  $\zeta(t)$  has no roots (which occurs only when dim X is even), set  $\tau = \beta(l+1) + 1$ . If  $\zeta(t)$  has roots, let  $\alpha$  be the largest root of  $\zeta(t)$ , set  $\tau = \max\{\beta(l+1), \lceil \alpha \rceil\} + 1$ . Note that  $\tau$  is a positive rational number. Moreover, on  $[\tau, +\infty)$ ,  $\zeta(t)$  is a positive, increasing real function, and  $\vartheta(t)$  is a non-negative, non-decreasing real function.

Step 5. In this step, we conclude the proof. We see that

$$\vartheta(t) = \operatorname{vol}(A + t(K_X + B)) = \frac{1}{l^d} \operatorname{vol}(lA + tS),$$

for any  $S \sim_{\mathbb{Q}} l(K_X + B)$ . For each t such that  $A + t(K_X + B)$  is big, i.e.,  $\vartheta(t) > 0$ , we may choose  $S_t$  as the pullback of a sufficiently general element  $T_t \in |l(K_Z + B_Z + M_Z)|$  such that  $S_t \nsubseteq \mathbf{B}_+(lA + tS_t)$ . Then by Theorem 2.4, the function  $s \mapsto \operatorname{vol}(lA + tS_t + sS_t)$ 

is differentiable at s=0, let  $\vartheta'(t)$  be the derivative of  $\vartheta(t)$  with respect to t, we have

$$\left. l^d \vartheta'(t) = l^d \frac{\mathrm{d}}{\mathrm{d}s} \vartheta(t+s) \right|_{s=0} = \left. \frac{\mathrm{d}}{\mathrm{d}s} (\operatorname{vol}(lA + tS_t + sS_t)) \right|_{s=0} = d \operatorname{vol}_{X|S_t}(lA + tS_t).$$

Moreover, if  $t \geq \tau$  and if  $A + t(K_X + B)$  is big, we have

$$\vartheta'(t) = \frac{d}{l^d} \operatorname{vol}_{X|S_t}(lA + tS_t)$$

$$\leq \frac{d}{l} \operatorname{vol}((A + \frac{t}{l}S_t)|_{S_t})$$

$$= \frac{d}{l} \operatorname{vol}(A_{S_t} + \frac{t}{l+1}(K_{S_t} + B_{S_t}))$$

$$= \frac{d}{l}(A_{S_t} + \frac{t}{l+1}(K_{S_t} + B_{S_t}))^{d-1}$$

$$= \varsigma'(t),$$

where the third equality follows from the fact that  $A_{S_t} + \frac{t}{l+1}(K_{S_t} + B_{S_t})$  is ample on  $[\tau, +\infty)$ .

We claim that  $\vartheta(\tau) > 0$ . Otherwise,  $\vartheta(\tau) = 0$ , employing the same argument as in the last paragraph of Step 2, we can get a contradiction. We conclude that  $\vartheta(t) \ge \vartheta(\tau) > 0$  for all  $t > \tau$ .

Remark 3.10. In the case when dim X=2, by Zariski decomposition [Laz04, Theorem 2.3.19] [Eno20, Theorem 3.1], the volume of a big divisor should be greater than or equal to its self-intersection. Thus when dim X=2, Proposition 3.9 quickly follows from this fact. However, this property does not necessarily hold for higher-dimensional varieties. For example, let Y be a smooth 3-fold with  $K_Y$  ample, and  $\pi: X=\operatorname{Bl}_P Y\to X$  be the blowing up of Y at a closed point P. Then  $K_X=\pi^*K_Y+2E$ , where E is the exceptional divisor over  $P\in Y$ , and  $K_X$  is big. Therefore,  $\operatorname{vol}(K_X)=\operatorname{vol}(K_Y)=K_Y^3$ , but  $K_X^3=K_Y^3+8E^3=K_Y^3+8>\operatorname{vol}(K_X)$ .

**Proof of Theorem 1.5.** This directly follows from Theorem 3.8 and Proposition 3.9.

#### 4. Moduli spaces

In this section, we prove Theorem 1.7, that is, we show that there is a separated Deligne-Mumford stack of finite type parametrizing families of traditional stable minimal models and it admits a coarse moduli space. We refer readers to [Alp23] for the notions of algebraic spaces, algebraic stacks and Deligne-Mumford stacks.

Let  $d \in \mathbb{N}$ ,  $\Phi = \{a_1, a_2, \dots, a_m\}$ , where  $a_i \in \mathbb{Q}^{\geq 0}$ ,  $\Gamma \subset \mathbb{Q}^{\geq 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. In this section, we will fix these data.

4.1. Moduli stacks of traditional stable minimal models. The general strategy for constructing moduli stacks of varieties is to embed the varieties into a single projective space and then employ Hilbert scheme arguments. Moreover, the theory of relative

Mumford divisors developed in [Kol23] also works for varieties polarized by effective divisors. However, for varieties polarized by non-canonical line bundles, to obtain a universal object for these line bundles, we consider embedding the varieties into the product of two projective spaces, following the approach in [Vie95, Section 1.7].

For any (X, B),  $A \in \mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(k)$ , we will use the following lemma to produce two different very ample line bundles  $\mathcal{O}_X(L_1)$ ,  $\mathcal{O}_X(L_2)$  on X such that  $\mathcal{O}_X(L_1) \sim \mathcal{O}_X(L_2) \otimes A$ .

**Lemma 4.1.** Let  $d \in \mathbb{N}$ ,  $\Phi = \{a_1, a_2, \dots, a_m\}$ , where  $a_i \in \mathbb{Q}^{\geq 0}$ ,  $\Gamma \subset \mathbb{Q}^{\geq 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Let K be a field of characteristic zero. Then there exist natural number  $\tau$  and I depending only on  $d, \Phi, \Gamma, \sigma$  such that  $\tau \Phi \subset \mathbb{N}$  and they satisfy the following. For any  $(X, B), A \in \mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(K)$  and nef Cartier divisor M on X, we have

- $\tau(K_X+B)$  is a base point free divisor,  $A+\tau(K_X+B)$  is an ample Cartier divisor,
- Let  $L_M := I(A + \tau(K_X + B)) + M$ , then  $L_M$  is strongly ample, i.e.  $L_M$  is very ample and  $H^q(X, kL_M) = 0$  for any k, q > 0,

*Proof.* By the same argument as [Bir22, Proof of Lemma 10.2], it is enough to find  $\tau$  and I when  $K = \operatorname{Spec} \mathbb{C}$ . Note that A is a line bundle in our setting, hence by the proof of Theorem 1.5, there exist  $\tau$ ,  $I_0$  such that  $\tau(K_X + B)$  is base point free,  $A + \tau(K_X + B)$  is ample Cartier, and  $L_0 := I_0(A + \tau(K_X + B))$  is very ample.

After replacing  $I_0$  with a bounded multiple, we may assume that  $L_0 - (K_X + B)$  is nef and big. Let  $I = (d+2)I_0$  and  $\mathcal{F} := L_M - I_0(A + \tau(K_X + B))$ , then

$$H^i(X, \mathcal{F} \otimes L_0^{\otimes (-i)}) = 0$$

for all i > 0 by Kawamata-Viehweg vanishing theorem. Thus  $\mathcal{F}$  is 0-regular with respect to  $L_0$  ([Laz04, Definition 1.8.4]), and hence  $\mathcal{F}$  is base point free by [Laz04, Theorem 1.8.5]. Therefore,

$$L_M = L_0 + \mathcal{F}$$

is very ample by [Har77, Exercise II 7.5(d)]. Again we have  $L_M - (K_X + B)$  is nef and big, hence  $H^q(X, kL_M) = 0$  for any k, q > 0.

We study the behavior of some invariants of traditional stable minimal models in families.

**Lemma 4.2.** Let  $d \in \mathbb{N}$ ,  $\Phi = \{a_1, a_2, \dots, a_m\}$ , where  $a_i \in \mathbb{Q}^{\geq 0}$ ,  $\Gamma \subset \mathbb{Q}^{\geq 0}$  be a finite set,  $\sigma \in \mathbb{Q}[t]$  be a polynomial. Let I and  $\tau$  be the positive natural number as Lemma 4.1. Let  $(X, B = \sum_{i=1}^m a_i D_i), A \to S$  be a family of  $(d, \Phi, \Gamma, \sigma)$ -marked traditional stable minimal models over reduced Noetherian scheme S. Let  $L_1 := I(A + \tau(K_{X/S} + B)) + I(A + \tau(K_{X/S} + B)), L_2 := I(A + \tau(K_{X/S} + B)) + (I - 1)(A + \tau(K_{X/S} + B)) + \tau(K_{X/S} + B),$  and  $L_3 := L_1 + L_2$ , then for every  $k \in \mathbb{Z}_{>0}$ , the functions  $S \to \mathbb{Z}$  sending

- (1)  $s \mapsto h^0(X_s, kL_{j,s})$  for j = 1, 2, 3 and
- (2)  $s \mapsto \deg_{L_{3,s}}(D_{i,s}) \text{ for } i = 1, 2, \dots, m$

are locally constant on S, where  $\deg_{L_{3,s}}(D_{i,s}) := D_{i,s} \cdot L_{3,s}^{d-1}$ .

*Proof.* (1). For j = 1, 2, 3,  $L_j$  are strongly ample over S by Lemma 4.1, it is enough to show that  $L_i$  are flat over S. Since  $X \to S$  is flat, it suffices to show that  $\mathcal{O}_X(L_i)$  are line bundles by [Har77, Proposition III 9.2(c)(e)].

Since  $(X, B) \to S$  is locally stable family and  $\mathcal{O}_{X_s}(\tau(K_{X_s} + B_s))$  is base point free for any  $s \in S$ , we see that  $\tau(K_{X/S} + B)$  is  $\mathbb{Q}$ -Cartier and  $\mathcal{O}_X(\tau(K_{X/S} + B))$  is a mostly flat family ([Kol23, Definition 3.26]) of line bundles. By [Kol23, Corollary 4.34 and Proposition 5.29],  $\mathcal{O}_X(\tau(K_{X/S} + B))$  is a line bundle. Moreover, since A is a line bundle on X, so  $\mathcal{O}_X(L_j)$  are line bundles for j = 1, 2, 3.

(2). It follows from [Kol23, Theorem 
$$4.3.5$$
].

We recall the definition of stacks [Alp23, Definition 2.4.1 and Exercise 2.4.4]. Let **Sets** be the category of sets and  $\mathbf{Sch}_S$  the category of schemes over S. If  $S = \operatorname{Spec} k$ , we denote  $\mathbf{Sch}$ .

**Definition 4.3** (Stack). Let  $p: \mathfrak{X} \to \mathbf{Sch}$  be a category fibered in groupoids.  $\mathfrak{X}$  is called a stack if the following two conditions hold.

(1) (morphisms glue) For any scheme  $S \in \mathbf{Sch}$  and any two objects  $a, b \in \mathfrak{X}(S) := p^{-1}(S)$ , the presheaf  $\mathfrak{Isom}_S(a, b) : \mathbf{Sch}_S \to \mathbf{Sets}$  defined by

$$\mathfrak{Isom}_S(a,b)(f:T\to S) = \mathrm{Isom}_T(f^*a,f^*b)$$

is an étale sheaf.

(2) (objects glue) For any étale covering  $S' \to S$  of an object  $S \in \mathbf{Sch}$ , any descent data with respect to this covering is effective: for objects  $a_i$  over  $S_i$  and isomorphisms  $\alpha_{ij}: a_i|_{S_{ij}} \to a_j|_{S_{ij}}$ , which satisfy the cocycle condition

$$\alpha_{jk}|_{S_{ijk}} \circ \alpha_{ij}|_{S_{ijk}} = \alpha_{ik}|_{S_{ijk}}$$

on  $S_{ijk}$ , then there exists an object a over S and isomorphisms  $\Phi_i : a|_{S_i} \to a_i$  over  $\mathrm{id}_{S_i}$  such that  $\Phi_i|_{S_{ij}} = \Phi_j|_{S_{ij}} \circ \alpha_{ij}$  on  $S_{ij}$ .

**Lemma 4.4.**  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is a stack.

Proof. Take two objects  $f:(X,B), A \to S$  and  $f':(X',B'), A' \to S$  in  $\mathfrak{TS}_{klt}(d,\Phi,\Gamma,\sigma)$ . For i=1,2, let  $\mathcal{O}_X(L_i)$  and  $\mathcal{O}_{X'}(L_i')$  be the relatively strongly ample line bundles as Lemma 4.2. Let  $\mathbb{P}=\mathbb{P}(f_*\mathcal{O}_X(L_1))\times_S\mathbb{P}(f_*\mathcal{O}_X(L_2))$  and  $\mathbb{P}'=\mathbb{P}(f_*'\mathcal{O}_{X'}(L_1'))\times_S\mathbb{P}(f_*'\mathcal{O}_{X'}(L_2'))$ . Then

$$\mathfrak{Isom}_S((X,B),(X',B')) \hookrightarrow \mathfrak{Isom}_S(\mathbb{P},\mathbb{P}')$$

is a closed immersion, where the presheaf  $\mathfrak{Isom}_S(\mathbb{P},\mathbb{P}')$ :  $\mathbf{Sch}_S \to \mathbf{Sets}$  is defined by

$$\mathfrak{Isom}_S(\mathbb{P}, \mathbb{P}')(T) = \mathrm{Isom}_T(\mathbb{P} \times_S T, \mathbb{P}' \times_S T).$$

Moreover, let  $H := \text{Hilb}_S(\mathbb{P} \times_S \mathbb{P}')$  and U be the universal family over H, then  $\mathfrak{Isom}_S(\mathbb{P}, \mathbb{P}')$  is represented by a locally closed subscheme of H [FGI<sup>+</sup>05, Theorem 5.23]. Furthermore,

 $\mathfrak{Isom}_S(f,f') \hookrightarrow \mathfrak{Isom}_S((X,B),(X',B'))$  is a closed immersion by the following Cartesian diagram

$$\mathfrak{Isom}_{S}(f,f') \longrightarrow \mathfrak{Isom}_{S}((X,B),(X',B'))$$

$$\downarrow \qquad \qquad \downarrow$$

$$\operatorname{Pic}_{U/H} \xrightarrow{\Delta} \operatorname{Pic}_{U/H} \times_{H} \operatorname{Pic}_{U/H}$$

and separatedness of the relative Picard scheme  $Pic_{U/H}$  [FGI<sup>+</sup>05, Theorem 9.4.8]. Hence  $\mathfrak{Isom}_S(f, f')$  is represented by a scheme, in particular, it is an étale sheaf.

Given any étale covering  $S' \to S$ , where  $(f': (X', B'), A' \to S') \in \mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(S')$ . To prove that f' descends to  $(f: (X, B), A \to S) \in \mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(S)$ , we use the strongly f'-ample line bundles  $\mathcal{O}'_X(L'_1)$  and  $\mathcal{O}'_X(L'_2)$  as Lemma 4.2 instead of  $\omega^{\otimes 3}_{\mathcal{C}'/S'}$  in [Alp23, Proposition 2.4.13]. The same argument as in *loc.cit*. implies that  $(X', B') \to S'$  descends to  $(X, B) \to S$ . Moreover, by applying [Alp23, Proposition B.1.4(2) and Proposition B.1.11] to the étale covering  $X' \to X$ , A' descends to a line bundle A on X. Every geometric fiber of  $f: (X, B), A \to S$  is identified with a geometric fiber of  $f': (X', B'), A' \to S'$ , thus  $(f: (X, B), A \to S) \in \mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)(S)$ .

Now we are ready to prove the main result of this subsection.

**Theorem 4.5.**  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is an algebraic stack of finite type.

*Proof.* The strategy for the construction of moduli stacks is standard, we outline the main points of the proof here. In Steps 1 to 3, we fix certain invariants and employ a Hilbert scheme argument along with the theory of relative Mumford divisors to obtain a scheme that parametrizes the total spaces and the relevant boundary divisors. Moving on to Steps 4 to 7, we will shrink the parametrizing space to cut the locus of interest for our moduli problem, ensuring that these loci are locally closed. In the final step, we study the group action of the locus under consideration and conclude the proof using stack theory.

Step 1. Let  $f:(X,B), A \to S$  be a family of  $(d,\Phi,\Gamma,\sigma)$ -traditional stable minimal models, where S is a reduced scheme. For j=1,2,3, let  $L_j$  be the Cartier divisor defined in Lemma 4.2, then  $L_j$  are strongly ample over S by Lemma 4.1.

Fixed  $n, l \in \mathbb{Z}$ ,  $\mathbf{c} = (c_1, c_2, \dots, c_m) \in \mathbb{N}^m$  and  $h \in \mathbb{Q}[k]$ , consider the subfunctor  $\mathfrak{TS}_{h,n,l,\mathbf{c}} \subset \mathfrak{TS}_{klt}(d,\Phi,\Gamma,\sigma)$  parametrizing families of  $(d,\Phi,\Gamma,\sigma)$ -traditional stable minimal models satisfying

- the Hilbert polynomial of  $X_s$  with respect to  $L_{3,s}$  is h,
- $h^0(X_s, L_{1,s}) 1 = n$ ,
- $h^0(X_s, L_{2,s}) 1 = l$ , and
- $(\deg_{L_{3,s}}(D_{1,s}), \deg_{L_{3,s}}(D_{2,s}), \dots, \deg_{L_{3,s}}(D_{m,s})) = \mathbf{c}$

for every  $s \in S$ .

By Theorem 1.5, there are finitely many possibilities for the Hilbert functions

$$h_s(k) = \chi(X_s, kL_{3,s}) = h^0(X_s, kL_{3,s})$$

of  $X_s$  with respect to  $L_{3,s}$ , and for  $1 \leq i \leq m$ , the numbers

$$n_s = h^0(X_s, L_{1,s}) - 1$$
,  $l_s = h^0(X_s, L_{2,s}) - 1$  and  $c_i = \deg_{L_{3,s}}(D_{i,s})$ 

belong to a finite set (the finiteness can be reduced to the case when  $s = \operatorname{Spec} \mathbb{C}$  by the same argument as [Bir22, Proof of Lemma 10.2]). Furthermore, by Lemma 4.2, for  $1 \leq i \leq m$ ,  $n_s$ ,  $l_s$ ,  $c_i$  and  $h_s$  are locally constant on S. Therefore, we can write

$$\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma) = \bigsqcup_{h.n.l} \mathfrak{TS}_{h,n,l,\mathbf{c}}$$

as disjoint union, and each  $\mathfrak{TS}_{h,n,l,\mathbf{c}}$  is a union of connected components of  $\mathfrak{TS}_{klt}(d,\Phi,\Gamma,\sigma)$ . Moreover, there are only finitely many  $n,l \in \mathbb{Z}_{>0}$ , and  $h \in \mathbb{Q}[k]$  such that  $\mathfrak{TS}_{h,n,l,\mathbf{c}}$  is not empty.

Step 2. Fixing  $n, l \in \mathbb{Z}$ ,  $\mathbf{c} = (c_1, c_2, \dots, c_m) \in \mathbb{N}^m$  and  $h \in \mathbb{Q}[k]$ , for any  $(f : (X, B), A \to S) \in \mathfrak{TS}_{h,n,l,\mathbf{c}}(S)$ , we see that  $\mathcal{O}_X(L_1)$  and  $\mathcal{O}_X(L_2)$  are strongly f-ample line bundles on X, we get an embedding

$$X \hookrightarrow \mathbb{P}(f_*\mathcal{O}_X(L_1)) \times_S \mathbb{P}(f_*\mathcal{O}_X(L_2)).$$

We proceed to parametrize such embedding.

Let  $H = \operatorname{Hilb}_h(\mathbb{P}^n \times \mathbb{P}^l)$  be the Hilbert scheme parametrizing closed subschemes of  $\mathbb{P}^n \times \mathbb{P}^l$  with Hilbert polynomial h. Let  $X_H = \operatorname{Univ}_h(\mathbb{P}^n \times \mathbb{P}^l) \stackrel{i}{\hookrightarrow} \mathbb{P}^n \times \mathbb{P}^l \times H$  be the universal family over H, and

$$\mathbb{P}^n \stackrel{p_1}{\leftarrow} \mathbb{P}^n \times \mathbb{P}^l \times H \stackrel{p_2}{\rightarrow} \mathbb{P}^l.$$

be the natural projections. Note that the  $\operatorname{PGL}_{n+1} \times \operatorname{PGL}_{l+1}$  action on  $\mathbb{P}^n \times \mathbb{P}^l$  induces a  $\operatorname{PGL}_{n+1} \times \operatorname{PGL}_{l+1}$  action on H. Let  $L_{3,H} := i^* \mathcal{O}_{\mathbb{P}^n \times \mathbb{P}^l \times H}(1,1)$  and  $A_H := i^* \mathcal{O}_{\mathbb{P}^n \times \mathbb{P}^l \times H}(1,-1)$  be the universal line bundles on  $X_H$ .

Step 3. By [Gro66, Theorem 12.2.1 and Theorem 12.2.4], the locus  $s \in H$  such that  $X_s$  is geometrically connected and reduced, equidimensional, and geometrically normal is an open subscheme  $H_1$  of H. Let  $L_{3,H_1}$  be the pull back of universal line bundle  $L_{3,H}$  over H to  $H_1$ .

Next, we parametrize the boundary divisors in the moduli problem. Since  $f_1: X_{H_1} \to H_1$  is equidimensional, and over reduced bases relative Mumford divisors are the same as K-flat divisors [Kol23, Definition 7.1 and comment 7.4.2], there is a separated  $H_1$ -scheme MDiv $_c(X_{H_1}/H_1)$  of finite type which parametrizes relative Mumford divisors of degree c with respect to  $L_{H_1}$  by [Kol23, Theorem 7.3]. Fixing  $\mathbf{c} = (c_1, c_2, \ldots, c_m) \in \mathbb{N}^m$ , let

$$H_2 := \mathrm{MDiv}_{c_1}(X_{H_1}/H_1) \times_{H_1} \mathrm{MDiv}_{c_2}(X_{H_1}/H_1) \times_{H_1} \cdots \times_{H_1} \mathrm{MDiv}_{c_m}(X_{H_1}/H_1)$$

be the m-fold fiber product, we denote the universal family by

$$(X_{H_2}, B_{H_2} = \sum_{i=1}^{m} a_i D_{i,H_2}; L_{3,H_2}), A_{H_2} \to H_2,$$

where  $D_{i,H_2}$  are the universal families of relative Mumford divisors on  $X_{H_2}$  of degree  $c_i$  for  $1 \le i \le m$ . Again the  $\operatorname{PGL}_{n+1} \times \operatorname{PGL}_{l+1}$  action on  $\mathbb{P}^n \times \mathbb{P}^l$  induces a  $\operatorname{PGL}_{n+1} \times \operatorname{PGL}_{l+1}$  action on  $H_2$ .

Step 4. By [Kol23, Theorem 4.8], there is a locally closed partial decomposition  $H_3 \to H_2$  satisfying the following: for any reduced scheme W and morphism  $q: W \to H_2$ , then the family obtained by base change  $f_W: (X_W, B_W) \to W$  is locally stable iff q factors as  $q: W \to H_3 \to H_2$ .

Since  $f_3:(X_{H_3},B_{H_3})\to H_3$  is locally stable, By [Kol23, Theorem 4.28], there is a locally closed partial decomposition  $H_4\to H_3$  satisfying the following: for any reduced scheme W and morphism  $q:W\to H_3$ , the divisorial pullback of  $\tau(K_{X_{H_3}/H_3}+B_{H_3})$  to  $W\times_{H_3}X_{H_3}$  is Cartier iff q factors as  $q:W\to H_4\to H_3$ .

Step 5. Since the fibers  $X_s$  of  $f_4: X_{H_4} \to H_4$  are reduced and connected by Step 3, we have  $h^0(X_s, \mathcal{O}_{X_s}) = 1$ . Since  $\tau(K_{X_{H_4}/H_4} + B_{H_4})$  is Cartier, by [Vie95, Lemma 1.19], there is a locally closed subscheme  $H_5 \subset H_4$  with the following property: for any scheme W and morphism  $q: W \to H_4$ ,

$$\mathcal{O}_{X_W}(1,0) \sim_W A_W^{2I} \otimes \omega_{X_W/W}^{[2I\tau]}(2I\tau B_W)$$
, and

$$\mathcal{O}_{X_W}(0,1) \sim_W A_W^{2I-1} \otimes \omega_{X_W/W}^{[2I\tau]}(2I\tau B_W)$$

iff q factors as  $q: W \to H_5 \to H_4$ , where  $\mathcal{O}_{X_W}(1,0)$  and  $\mathcal{O}_{X_W}(0,1)$  are the pullbacks of  $\mathcal{O}_{\mathbb{P}^n \times \mathbb{P}^l \times H_4}(1,0)$  and  $\mathcal{O}_{\mathbb{P}^n \times \mathbb{P}^l \times H_4}(0,1)$  to  $X_W$ , respectively.

Step 6. By [Bir22, Lemma 8.5], there is a locally closed subscheme  $H_6 \subset H_5$  such that for any  $s \in H_6$ ,  $K_{X_s} + B_s$  is semi-ample defining a contraction  $X_s \to Z_s$ .

Since ampleness and klt are open conditions, there is an open subscheme  $H_7 \subset H_6$  such that  $A_s + \tau(K_{X_s} + B_s)$  is ample and  $(X_s, B_s)$  is klt for any  $s \in H_7$ .

By [Har77, Theorem III 12.8], there is an open subscheme  $H_8 \subset H_7$  such that for any  $s \in H_8$ ,

$$H^{q}(X_{s}, 2IA_{s} + 2I\tau(K_{X_{s}} + B_{s})) = H^{q}(X_{s}, (2I - 1)A_{s} + 2I\tau(K_{X_{s}} + B_{s})) = 0$$

for any q > 0. Thus by [Har77, Theorem III 12.11], for any  $s \in H_8$ ,

$$h^0(X_s, 2IA_s + 2I\tau(K_{X_s} + B_s)) = n + 1$$
, and

$$h^{0}(X_{s}, (2I-1)A_{s} + 2I\tau(K_{X_{s}} + B_{s})) = l + 1.$$

Therefore,  $f_{8*}(A_{H_8}^{2I} \otimes \omega_{X_{H_8}/H_8}^{[2I\tau]}(2I\tau B_{H_8}))$  and  $f_{8*}(A_{H_8}^{2I-1} \otimes \omega_{X_{H_8}/H_8}^{[2I\tau]}(2I\tau B_{H_8}))$  are locally free sheaves of rank n+1 and l+1, respectively. Shrinking  $H_8$ , we may assume that they are free sheaves, and hence

$$\mathbb{P}(f_{8*}(A_{H_8}^{2I} \otimes \omega_{X_{H_8}/H_8}^{[2I\tau]}(2I\tau B_{H_8}))) \cong \mathbb{P}_{H_8}^n$$
, and

$$\mathbb{P}(f_{8*}(A_{H_8}^{2I-1} \otimes \omega_{X_{H_8}/H_8}^{[2I\tau]}(2I\tau B_{H_8}))) \cong \mathbb{P}^l_{H_8}.$$

Step 7. By [Bir22, Lemma 8.7] (the condition of  $A_s$  being effective is not required in the proof), there is a locally closed subscheme  $H_9 \subset H_8$  such that for any  $s \in H_9$ ,  $\operatorname{vol}(A_s|_F) \in \Gamma$  for the general fibres F of  $X_s \to Z_s$ .

For each  $s \in H_9$ , since  $K_{X_s} + B_s$  is nef and  $A_s + \tau(K_{X_s} + B_s)$  is ample,  $K_{X_s} + B_s + tA_s$  is ample for each  $t \in (0, \frac{1}{s}]$ , then

$$\theta_s(t) = \text{vol}(K_{X_s} + B_s + tA_s) = (K_{X_s} + B_s + tA_s)^d$$

is a polynomial in t of degree  $\leq d$  on the interval  $(0, \frac{1}{\tau}]$ . By Step 3(iv) of [Bir22, Proof of Proposition 9.5], there is an open and closed subscheme  $H_{10} \subset H_9$  such that  $\theta_s(t) = \sigma(t)$  on the interval  $(0, \frac{1}{\tau}]$ .

Step 8. By our construction,  $H_{10}$  represents the category fibered over **Sch** whose objects consist of a family  $f: (X \subset \mathbb{P}^n \times \mathbb{P}^l \times S, B), A \to S$  with isomorphisms  $\mathbb{P}(f_*(A_S^{2I} \otimes \omega_{X_S/S}^{[2I\tau]}(2I\tau B_S))) \cong \mathbb{P}_S^n$  and  $\mathbb{P}(f_*(A_S^{2I-1} \otimes \omega_{X_S/S}^{[2I\tau]}(2I\tau B_S))) \cong \mathbb{P}_S^l$ . We claim that

$$\mathfrak{TS}_{h,n,l,\mathbf{c}} \cong [H_{10}/\mathrm{PGL}_{n+1} \times \mathrm{PGL}_{l+1}].$$

We follow the arguments of [Alp23, Theorem 3.1.17] and [ABB<sup>+</sup>23, Proposition 3.9]. Indeed, note that the universal family

$$(X_{H_{10}} \subset \mathbb{P}^n \times \mathbb{P}^l \times H_{10}, B_{H_{10}} = \sum_{i=1}^m a_i D_{i,H_{10}}), A_{H_{10}} \to H_{10}$$

is an object in  $\mathfrak{TS}_{h,n,l,\mathbf{c}}(H_{10})$ , which induces a morphism  $H_{10} \to \mathfrak{TS}_{h,n,l,\mathbf{c}}$ , where this morphism just forgets the projective embeddings. Moreover, this morphism is  $\mathrm{PGL}_{n+1} \times \mathrm{PGL}_{l+1}$ -invariant, hence descends to a morphism  $\Psi^{\mathrm{pre}} : [H_{10}/\mathrm{PGL}_{n+1} \times \mathrm{PGL}_{l+1}]^{\mathrm{pre}} \to \mathfrak{TS}_{h,n,l,\mathbf{c}}$  of prestacks. Since  $\mathfrak{TS}_{h,n,l,\mathbf{c}}$  is a stack by Lemma 4.4, the universal property of stackification [Alp23, Theorem 2.4.17] yields a morphism  $\Psi : [H_{10}/\mathrm{PGL}_{n+1} \times \mathrm{PGL}_{l+1}] \to \mathfrak{TS}_{h,n,l,\mathbf{c}}$ .

To show  $\Psi$  is fully faithful, by [Alp23, Exercise 2.4.16], it suffices to check that  $\Psi^{\text{pre}}$  is fully faithful. To see this, let  $S \to H_{10}$  be a map corresponding to the family  $f: (X \subset \mathbb{P}^n \times \mathbb{P}^l \times S, B), A \to S$ . We see that an automorphism of  $f: (X, B), A \to S$  induces an automorphism of  $\mathcal{O}_X(L_1)$  and  $\mathcal{O}_X(L_2)$ , which in turn induces an automorphism of

$$\mathbb{P}(f_*\mathcal{O}_X(L_1)) \times_S \mathbb{P}(f_*\mathcal{O}_X(L_2)) \cong \mathbb{P}_S^n \times_S \mathbb{P}_S^l \cong \mathbb{P}^n \times \mathbb{P}^l \times S$$

preserving  $(X, B), A \to S$ .

It remains to check that  $\Psi$  is essentially surjective. Consider  $(f:(X,B),A\to S)\in \mathfrak{TS}_{h,n,l,\mathbf{c}}(S)$ , since  $f_*\mathcal{O}_X(L_1)$  and  $f_*\mathcal{O}_X(L_2)$  are locally free, there exists an open cover  $S=\cup_i S_i$  over which their restrictions are free. Choosing trivializations induce embeddings  $g_i:(X_{S_i},B_{S_i})\hookrightarrow \mathbb{P}^n\times \mathbb{P}^l\times S_i$ . Moreover, for any  $s\in S_i$ , since  $A_s\sim g_{i,s}^*\mathcal{O}_{\mathbb{P}^n_{k(s)}\times\mathbb{P}^l_{k(s)}}(1,-1)$ , where  $g_{i,s}=g_i|_{X_s}:(X_s,B_s)\hookrightarrow \mathbb{P}^n_{k(s)}\times \mathbb{P}^l_{k(s)}$ , we have  $A_{S_i}\sim_{S_i}g_i^*\mathcal{O}_{\mathbb{P}^n\times\mathbb{P}^l\times S_i}(1,-1)$  by [Har77, Exercise III 12.4]. Hence by our construction of  $H_{10}$ , we have morphisms  $\Phi_i:S_i\to H_{10}$ . Over the intersections  $S_i\cap S_j$ , the trivializations differ by a section  $s_{ij}\in H^0(S_i\cap S_j,\mathbb{P}GL_{n+1}\times\mathbb{P}GL_{l+1})$ . Therefore the  $\Phi_i$  glue to a morphism  $\Phi:S\to [H_{10}/\mathbb{P}GL_{n+1}\times\mathbb{P}GL_{l+1}]$ , which induces a morphism  $\mathfrak{TS}_{h,n,l,\mathbf{c}}\to [H_{10}/\mathbb{P}GL_{n+1}\times\mathbb{P}GL_{l+1}]$ , that is the inverse of  $\Psi$ .

Note that  $H_{10}$  is a finite type scheme, thus  $\mathfrak{TS}_{h,n,l,\mathbf{c}} \cong [H_{10}/\mathrm{PGL}_{n+1} \times \mathrm{PGL}_{l+1}]$  is a finite type algebraic stack. Taking the disjoint union over all  $h, n, l, \mathbf{c}$  yields  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$ .

4.2. Moduli spaces of traditional stable minimal models. In this subsection, we prove Theorem 1.7. We need the following separatedness result to construct moduli spaces of traditional stable minimal models. Before stating the result, we review some notations.

Let C be an affine curve. Let  $f:(X,B), A \to C$  and  $f':(X',B'), A' \to C$  be two families of  $(d,\Phi,\Gamma,\sigma)$ -traditional stable minimal models over C. We put

$$((X,B),A) \times_C C^o = (X \times_C C^o, B \times_C C^o), A|_{X \times_C C^o}.$$

We define  $g:(X,B), A \to (X',B'), A'$  to be a C-isomorphism  $g:X \to X'$  such that  $f' \circ g = f$ ,  $g_*B = B'$  and  $g^*A' \sim_C A$ . We define  $C^o$ -isomorphisms between  $((X,B),A) \times_C C^o$  and  $((X',B'),A') \times_C C^o$  similarly.

**Theorem 4.6** ([Bou14, Theorem 2.1], [HH23, Proposition 4.4]). Let C be an affine curve. Let  $f:(X,B), A \to C$  and  $f':(X',B'), A' \to C$  be two families of  $(d,\Phi,\Gamma,\sigma)$ -traditional stable minimal models over C. Let  $0 \in C$  be a closed point and  $C^o = C \setminus \{0\}$  the punctured curve. Suppose that there exists a  $C^o$ -isomorphism

$$g^o: ((X,B),A) \times_C C^o \to ((X',B'),A') \times_C C^o$$

then  $g^{\circ}$  can be extended to a C-isomorphism  $g:(X,B),A\to (X',B'),A'$ .

Proof. Consider  $L := A' + \tau(K_{X/C} + B)$  and  $L' := A' + \tau(K_{X'/C} + B')$ , where  $\tau$  is a positive natural number as Lemma 4.1. By the proof of Lemma 4.2, L is a f-ample Cartier divisor on X (resp. L' is a f'-ample Cartier divisor on X'). Let  $g: X \dashrightarrow X'$  be the birational map induced by  $g^o$ , then by the same argument as in [HH23, Proof of Proposition 4.4], g is a C-isomorphism.

The following corollary follows from Theorem 4.6 and the argument of [BX19, Proof of Corollary 3.5]. We include the proof for convenience.

Corollary 4.7. Let (X, B), A be a  $(d, \Phi, \Gamma, \sigma)$ -traditional stable minimal model. Then  $\operatorname{Aut}((X, B), A)$  is finite.

*Proof.* Since  $\operatorname{Aut}((X,B),A)$  is a linear algebraic group, it is affine. To conclude that  $\operatorname{Aut}((X,B),A)$  is finite, it suffices to show that it is proper. To see the properness, consider a map  $g^o: C^o \to \operatorname{Aut}((X,B),A)$ , where  $0 \in C$  is a smooth pointed curve and  $C^o = C \setminus \{0\}$ . The map  $g^o$  induces an isomorphism

$$((X \times C, B \times C), A \times C) \times_C C^o \to ((X \times C, B \times C), A \times C) \times_C C^o$$

over  $C^o$ . By applying Theorem 4.6 to the above isomorphism, we see  $g^o$  extends to a map  $g: C \to \operatorname{Aut}((X,B),A)$ . Hence,  $\operatorname{Aut}((X,B),A)$  is proper, and the proof is complete.  $\square$ 

**Proof of Theorem 1.7.** By Theorem 4.5,  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is an algebraic stack of finite type. By Corollary 4.7 and [Alp23, Theorem 3.6.4],  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is a Deligne-Mumford

stack. Moreover, Theorem 4.6 and [Alp23, Theorem 3.8.2(3)] imply that  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  is a separated Deligne-Mumford stack. Therefore, we may apply Keel-Mori Theorem [KM97][Alp23, Theorem 4.3.12] to see that  $\mathfrak{TS}_{klt}(d, \Phi, \Gamma, \sigma)$  has a coarse moduli space  $TS_{klt}(d, \Phi, \Gamma, \sigma)$ , which is a separated algebraic space.
